Introduction to the quest of a sound FFI for Coq

Foreign Functions as Non-Deterministic Functions

Coq “Theorems for Free” about Polymorphic Foreign Functions

Applications to Certify UNSAT Answers from Oracles

Several kinds of Foreign Functions in Coq programs

1. Extend Coq with I/O, exceptions & threads.
Already possible with <http://coq.io/>
⇒ provides support to reason about I/O effects in Coq.
⇒ efficiently *extracted* to OCAML.
2. Introduce *external oracles* in complex computations
e.g. “*register allocation*” of COMPCERT (see next slides).
No reasoning on their effects, only on returned values !
3. More generally : interoperability with external systems.
What do we need : oracles + axioms on oracles ?
or, something more specific to each external system ?

This talk = kind 2 : “foreign functions” as “untrusted oracles”

Foreign Functions in Coq : an Unsound Example

Standard method to declare a foreign function in Coq

“Use an axiom declaring its type; replace this axiom at extraction”

```

Definition one: nat := (S 0).

Axiom oracle: nat → bool.

Lemma congr: oracle one = oracle (S 0).
  auto.

Qed.
  
```

With the OCAML implementation “let oracle x = (x == one)”

Unsound! Because at runtime, (oracle one) returns true whereas (oracle (S 0)) returns false.

Reason OCAML “functions” are not functions in the math sense. They are rather “non-deterministic functions” (ie “relations”)

NB $\mathbb{P}(A \times B) \simeq A \rightarrow \mathbb{P}(B)$ where “ $\mathbb{P}(B)$ ” is “ $B \rightarrow \mathbf{Prop}$ ”

Oracles in success of COMPCERT [Leroy et al., 2006-2018]

Success story of software certification in Coq :

the safest C optimizing compiler [Yang et al., 2011]

commercially available since 2015

compile critical software for airplanes & power plants.

Uses “untrusted oracles” invoked from the certified code.

Example of *register allocation* – a NP-complete problem

- finding a *correct* and *efficient* allocation is difficult
 - verifying the *correctness* of an allocation is easy
- ⇒ Only “*allocation checking*” is certified in Coq

Benefits of untrusted oracles

simplicity + efficiency + modularity

Issues of oracles in COMPCERT

Oracles are declared as pure functions.

Example of register allocation :

```
Axiom regalloc: RTL.func → option LTL.func.
```

Not a real issue because

their purity is not used in the compiler proof !

This talk proposes an approach to ensure such a claim...

The quest proposed in this talk

Define a class “*permissive*” of COQ types and a class “*safe*” of OCAML constants such that

a COQ type T is “*permissive*” iff
 any “*safe*” constant compatible with the extraction of T
 is soundly axiomatized in COQ with type T
 (for partial correctness)

with “*being permissive*” and “*being safe*” automatically checkable
 and as expressive as possible!

This could lead to a COQ “**Import Constant**” construct

```
Import Constant ident: permissive_type
:= "safe_ocaml_constant".
```

that acts like “**Axiom** ident: permissive_type”,
 but with additional checks during COQ and OCAML typechecking.

Introduction to the quest of a sound FFI for Coq

Foreign Functions as Non-Deterministic Functions

Coq “Theorems for Free” about Polymorphic Foreign Functions

Applications to Certify UNSAT Answers from Oracles

May-Return Monads [Fouilhé, Boulmé'14]

Axiomatize “ $\mathbb{P}(A)$ ” as type “ $??A$ ”

to represent “*impure computations of type A* ”

and “ $a \in k$ ” as proposition “ $k \rightsquigarrow a$ ”

read “*computation k may return value a* ”

with formal type $\rightsquigarrow_A: ??A \rightarrow A \rightarrow \text{Prop}$

Formal operators and axioms

▶ $\text{ret}_A : A \rightarrow ??A$ *(interpretable as identity relation)*

$$(\text{ret } a_1) \rightsquigarrow a_2 \rightarrow a_1 = a_2$$

▶ $\gg=_{A,B} : ??A \rightarrow (A \rightarrow ??B) \rightarrow ??B$

(interpretable as the image of a predicate by a relation)

$$(k_1 \gg= k_2) \rightsquigarrow b \rightarrow \exists a, k_1 \rightsquigarrow a \wedge k_2 a \rightsquigarrow b$$

encodes OCAML “**let** $x = k_1$ **in** k_2 ” as “ $k_1 \gg= (\text{fun } x \Rightarrow k_2)$ ”

NB another interpretation is “ $??A := A$ ” used for extraction !

Usage of May-Return Monads

Used to declare oracles in the Verified Polyhedra Library
[Fouilhé, Maréchal et. al, 2013-2018]

However, soundness of VPL design is currently only a conjecture!

Example of Conjecture

“`nat → ??bool`” is *permissive* for any welltyped OCAML constant

NB For `oracle : nat → ??bool` the below property is not provable

$$\forall b b', (\text{oracle one}) \rightsquigarrow b \rightarrow (\text{oracle (S 0)}) \rightsquigarrow b' \rightarrow b = b'.$$

The issue of cyclic values

Consider the following COQ type

```
Inductive empty: Type := Absurd: empty → empty.
```

This type is proved to be empty. ($\text{Thm} : \text{empty} \rightarrow \text{False}$).

Then, a function of $\text{unit} \rightarrow ?? \text{empty}$ is proved to never return.

Thus, $\text{unit} \rightarrow ?? \text{empty}$ is not permissive in presence of OCAML cyclic values like

```
let rec loop: empty = Absurd loop
```

My proposal

Add an optional tag on OCAML type definitions to **forbid** cyclic values (typically, for inductive types extracted from COQ).

Axioms of phys. equality also forbids cyclic values

In presence of the following axioms

```
Axiom phys_eq:  $\forall \{A\}, A * A \rightarrow ?? \text{bool}.$ 
Axiom phys_eq_true:  $\forall A (x\ y: A),$ 
  phys_eq(x,y)  $\rightsquigarrow$  true  $\rightarrow x=y.$ 
```

where `phys_eq (x,y)` is extracted on `x==y`,
the following OCAML value is unsound...

```
let rec fuel: nat = S fuel
```

since at runtime “`pred fuel == fuel`”,
whereas it is easy to prove the following COQ goal

```
Goal  $\forall (n:\text{nat}), \text{pred } n = n \rightarrow n = 0.$ 
```

and to write a COQ function distinguishing `fuel` from `0`.

Counter-Examples and Conjectures of “being permissive”

Here “safe” OCAML functions correspond to
 “well-typed” functions (without “obj.magic” tricks)
 and without cyclic-values on extracted types.

Counter-Examples the following types are not permissive

<code>nat → bool</code>	<code>(* extracted as nat → bool *)</code>
<code>nat → ??{ n:nat n ≤ 10}</code>	<code>(* nat → nat *)</code>
<code>nat → ??(nat → nat)</code>	<code>(* nat → (nat → nat) *)</code>

Conjecture the following types are permissive

<code>nat → ??(nat → ?? nat)</code>	<code>(* nat → (nat → nat) *)</code>
<code>{ n:nat n ≤ 10} → ?? nat</code>	<code>(* nat → nat *)</code>
<code>(nat → ?? nat) → ?? nat</code>	<code>(* (nat → nat) → nat *)</code>
<code>(nat → nat) → ?? nat</code>	<code>(* (nat → nat) → nat *)</code>
<code>∀ A, A*A → ??(list A)</code>	<code>(* 'a*'a → ('a list) *)</code>

Introduction to the quest of a sound FFI for Coq

Foreign Functions as Non-Deterministic Functions

Coq “Theorems for Free” about Polymorphic Foreign Functions

Applications to Certify UNSAT Answers from Oracles

A first “Theorem for Free” in Coq

Conjecturing that “ $\forall A, A \rightarrow ??A$ ” is permissive,
 we prove that any *safe* OCAML “`pid: 'a -> 'a`” satisfies
 when `(pid x)` returns normally some `y` then `y = x`.

Proof

```
Axiom pid:  $\forall A, A \rightarrow ??A$ .

(* We define below cpid:  $\forall \{B\}, B \rightarrow ?B$  *)
Program Definition cpid {B} (x:B): ?? B :=
  (pid { y | y = x } x) >>= (fun z => ret (proj1_sig z)).

Lemma cpid_correct A (x y:A): (cpid x)  $\rightsquigarrow$  y  $\rightarrow$  y=x.
```

At extraction, we get “`let cpid x = pid x`”.

Permissiveness of Polymorphism \Rightarrow Parametric Invariance

Permissiveness of

“ $\forall A, (A \rightarrow A \rightarrow A) \rightarrow ??(A \rightarrow ??(\text{list } A))$ ” implies that any safe OCAML

`foo: ('a -> 'a -> 'a) -> 'a -> ('a list)`

preserves any invariant (like $7\mathbb{N}$) attached to type variable 'a.

Example : “(foo (+) 7)” can only return lists of $7\mathbb{N}$.

A property of polymorphism sometimes called “unary parametricity”
or “*parametricity over unary logical relations*”

I prefer “*parametric invariance*”.

NB “theorems for free” from the type of polymorphic oracles !

Parametric Invariance for ML

- ▶ Comes *intuitively* from the type-erasure semantics : types are removed from runtime code (hence polymorphic functions must uniformly treat polymorphic values).
- ▶ Even hard to *formally define* :
What are “invariants” about a higher-order reference (which can thus refer to itself) ?
- ▶ Has been proved for a variant of system F with references by [Birkedal'11] (from the works of [Ahmed'02] and [Appel'07]).
- ▶ **Requires some restrictions** on polymorphic references
parametric invariance is unsound on function calls creating some alias on an effective argument !

Example on type “`int ref -> 'a ref -> 'a`”

```
let f x y = ( x:=0; !y )
```

Unsound Parametric Reasoning on “`f x x`” (returning 0).
 \Rightarrow forbids to “import” polymorphic references in Coq ???

Foreign Functions as Non-Deterministic Functions

Coq “Theorems for Free” about Polymorphic Foreign Functions

Applications to Certify UNSAT Answers from Oracles

Certifying UNSAT Answers from Oracles

Examples UNSAT on Boolean CNF or in linear arithmetic ; no valid register allocation ; etc...

Usually reduced to check some certificate (e.g. a resolution proof) from the oracle.

Alternatively might be done with Polymorphic LCF style :
Oracles computes directly “correct-by-construction” results
through an API certified from Coq
where type abstraction comes from polymorphism

Examples

- Since 2017, VPL fully rewritten in Polymorphic LCF style.

Benefits :

- ▶ Code size on the interface COQ/OCAML divided by 2 :
shallow versus deep embedding (of certificates).
- ▶ Interleaved execution of untrusted and certified computations :
Oracles debugging much easier.

See [Maréchal, Phd'17] or [Boulmé, Maréchal, preprint'17].

- **In this talk** : a *tiny* UNSAT prover on Boolean CNF
On the top of state-of-the-art CDCL SAT solvers + drat-trim
Based on verification of "*Backward Resolution Chains*"
(introduced as "*Restricted RUP*" by [Cruz-Filipe et al, 2016])
(*work in progress with Thomas Vandendorpe*)

Specification of the Refutation Prover

(Boolean) variable x (encoded as a positive).

Literal $\ell \triangleq x$ or $\neg x$.

Clause $C \triangleq$ a finite disjunction of literals
(encoded as a finite set of literals).

CNF $F \triangleq$ a finite conjunction of clauses
(encoded as a list of clauses).

```
unsat: list clause → ?? bool.
```

```
Lemma unsat_correct: ∀ F, (unsat F) ≈ true → ∀ m, ¬[[F]] m.
```

Background on Backward Resolution

Thm (Resolution proof system) F is UNSATISFIABLE
iff clause \emptyset is derivable from

$$\text{AXIOM} \frac{}{C} C \in F \qquad \text{RESOL} \frac{\{l\} \cup C'_1 \quad \{\neg l\} \cup C'_2}{C'_1 \cup C'_2}$$

Rule RESOL equivalently split in two rules for **backward checking**

$$\text{BCKRSL} \frac{\{l\} \cup C'_1 \quad \{\neg l\} \cup C}{C} C'_1 \subseteq C \qquad \text{TRIVIAL} \frac{C'_2}{C} C'_2 \subseteq C$$

equivalently rewritten in

$$\text{BCKRSL} \frac{C_1 \quad \{\neg l\} \cup C}{C} C_1 \setminus C = \{l\} \qquad \text{TRIVIAL} \frac{C_1}{C} C_1 \setminus C = \emptyset$$

Resolution Chains & Conflict-Driven Clause Learning DPLL

A **Backward Resolution Chain** (BRC) w.r.t a list of axioms F
 = specialization of BCKRSL and TRIVIAL when $C_1 \in F$

$$\text{UNIT} \frac{C_1 \quad \{\neg \ell\} \cup C}{C} \left\{ \begin{array}{l} C_1 \in F \\ C_1 \setminus C = \{\ell\} \end{array} \right. \quad \text{CONFLICT} \frac{C_1}{C} \left\{ \begin{array}{l} C_1 \in F \\ C_1 \setminus C = \emptyset \end{array} \right.$$

Other interpretation : two DPLL steps (read backward) where
 C is assumed FALSE (while F is assumed TRUE).

On CONFLICT , DPLL backtracks : it **learns** some clause C from F

$$= \left\{ \begin{array}{l} \text{it proves } "F \Rightarrow C" \text{ from} \\ \dots \\ \text{and then adds } C \text{ in } F \end{array} \right.$$

$$\text{UNIT} \frac{C_1 \quad \text{UNIT} \frac{C_{n-1} \quad \text{CONFLICT} \frac{C_n}{\dots}}{\dots}}{C}$$

CDCL **"minimizes"** C before learning !

UNSAT Certificates from Learned Clauses

- ▶ UNSAT answer when clause \emptyset is learned
- ▶ UNSAT certificates for CDCL in DRUP format
:= a sequence of learned clauses until \emptyset
(We also support RAT clauses : out the scope of this talk)
- ▶ The DRAT-TRIM tool of [Heule et al, 2013-2017] outputs a backward resolution chain $[C_1; \dots; C_n]$ for each learned clause C (LRAT format).

Learning Clauses in Coq from Backward Resolution Chains

On $F:(\text{list clause})$, define type $\text{cc}[[F]]$ of “consequences” of F .

```
Record cc(s:model → Prop): Type :=
  { rep: clause; rep_sat: ∀ m, s m → [[rep]] m }.
```

Then, we define emptiness test :

```
Definition isEmpty: ∀ {s}, cc s → boolean := ...
Lemma isEmpty_correct:
  ∀ s (c: cc s), isEmpty c=true → ∀ m, ¬(s m).
```

Learning a clause (from a BRC) is defined by

```
learn: ∀{s}, list(cc s) → clause → option(cc s)
```

such that $(\text{learn } l \ c)$ returns

- ▶ (Some c') with $(\text{rep } c')=c$ on a correct BRC.
- ▶ None otherwise.

Toward “*Logical Consequence Factories*” (LCF)

Idea our oracle (\approx a LRAT parser) computes directly “certified learned clauses” through a certified API (called a LCF).

\Rightarrow No need of an explicit “proof object” !

For the following benefits

- ▶ Backward Resolution Chains are verified “on-the-fly”, in the oracle (much easier to debug)
- ▶ very low memory footprint : deletion of “learned clauses” in memory directly & only managed by the oracle.
- ▶ very simple & small Coq code

Polymorphic LCF Style Oracle

- ▶ Data-abstraction is provided by polymorphism !
type `A` is abstract type of “learned clause”
here, `lcf` = abstraction of certified clause learning
- ▶ In input, each clause both given as a concrete value of `clause` and an abstract “axiom” of type `A`.
- ▶ On an UNSAT input, the oracle returns some *learned clause* (built from inputs and `lcf` operations) and we only check its emptiness.

```
Definition lcf A := (list A) → clause → option A.
```

```
Axiom oracle: ∀ {A}, (lcf A)*list(clause*A) → ??(option A).
```

Using the Polymorphic Oracle in Coq

Implementation of unsat

```

Definition mkInput (f: list clause):
  lcf(cc[[f]]) * list(clause*(cc[[f]]))
:= ...

```

```

Definition unsat f :=
  oracle (mkInput f) >>= (fun o =>
    ret (match o with
      | Some c => isEmpty c
      | None => false end)).

```

Good results from our first experiments on some “large” examples (from SAT-competition 2017)

Verifying Backward Resolution Chains with certified code from Coq is *faster* than the corresponding *SAT-solver run*...

(Partial) Conclusion

- ▶ Study of “Foreign Functions” in Coq
 \rightsquigarrow new proof paradigms, combining Coq and other tools

- ▶ I propose to combine Coq and OCaml typecheckers to get
 “Theorems for free!” *almost for free!*

- ▶ Only need to understand the meta-theory of this proposal
 Is there any interested type-theorist in the room?
